

Setting up your computer

NSDF-Data student guide 1 — Linux edition

Version 10 · 7 October 2026

Tip

Who this is for. You are starting from little or no computing experience. You will paste some commands into a terminal and read the answers. You do **not** need to know any programming. Work through the steps in order. Each step ends with a **Checkpoint**: if it does not match, stop there.

Before you start

- **Time:** about one hour. Most of it is waiting for downloads and installers.
- **You need:** an internet connection, the password for your computer, and about 3 GB of free disk space.
- **Rule of thumb:** type or paste commands **exactly** as written. Capitals and spaces matter.
- **Nothing to be afraid of:** the commands in this guide install software and make new folders. None of them deletes your files. If you are not sure what a line does, there is a short table after each group of commands.
- **When something goes wrong:** do not guess. Copy the message, note the step you were on, and ask the project lead. See *If something goes wrong* at the end.

Words you will meet

Word	What it means
Terminal	A window where you type commands and the computer answers in text.
Command	One line you type in the terminal, followed by Enter (or Return).
Folder (or directory)	A place on your computer that holds files and other folders.
Path	The address of a folder, such as C:\Users\YourName\Research.
Git	A program that downloads and keeps track of versions of code.
Repository (repo)	A project folder that Git tracks. Here, NSDF-Data.

Word	What it means
Python	The programming language the analysis is written in. You will not need to write Python to finish these guides.
Conda / Miniforge	A tool that installs Python and packages in separate, named <i>environments</i> .
Environment	A sealed set of programs and versions, so this project's software does not clash with others.
Package	A piece of ready-made software (for example <i>numpy</i>).
Jupyter notebook	A document that mixes text, code and plots, run one piece (<i>cell</i>) at a time.
Branch	A separate line of work in Git, so your changes do not touch the main code.

Step 1. Open a terminal

Press **Ctrl + Alt + T** (on Ubuntu), or search your applications for **Terminal**. A window with a text prompt opens. This is the terminal for everything in this guide.

Paste with **Ctrl + Shift + V** (plain Ctrl+V does not work in most terminals).

Checkpoint

You see a line of text ending in a symbol such as `>`, `$` or `%`. Type `echo hello` and press Enter: the word `hello` should appear under it.

Step 2. Install Git

This guide uses Ubuntu or Debian commands. If you use another distribution, use its package manager instead. Type:

```
sudo apt install git
```

It asks for your password. Nothing appears while you type it; that is normal. Press **Return**, then type `y` and press **Return** if it asks to continue.

Checkpoint

In the terminal, type `git --version` and press Enter. You should see a line starting with `git version`.

Step 3. Install Miniforge

Miniforge installs Python and the other packages the analysis needs. Its download file is **Miniforge3-Linux-x86_64.sh (most PCs)**.

Check your computer type with this command, which prints one word:

```
uname -m
```

x86_64 means the file below. aarch64 means an ARM computer: use **Miniforge3-Linux-aarch64.sh** instead.

Download the file into your **Downloads** folder: [Miniforge3-Linux-x86_64.sh](#), or [Miniforge3-Linux-aarch64.sh](#) for an ARM computer. Then install it with this command (use the file name you downloaded):

```
bash ~/Downloads/Miniforge3-Linux-x86_64.sh
```

Press **Return** to read the licence, type yes, accept the default location, and when it asks about running `conda init`, type yes. Then **close the terminal and open a new one**.

Checkpoint

Open a **new** terminal and type `conda --version`, then press Enter. You should see `conda` followed by a version number.

Careful

Use `sudo` only for the one command that installs Git. Other commands in this guide must not use it.

Step 4. Download the NSDF-Data code

Your project will live in a folder called `Research`. Create it, go into it, and download the code. Type each line and press Enter:

```
mkdir -p ~/Research
cd ~/Research
git clone https://github.com/villano-lab/NSDF-Data.git
cd ~/Research/NSDF-Data
```

Downloading with `git clone` does not need a GitHub account. It makes a full copy of the project in a folder named `NSDF-Data`.

What these lines do

Line starts with	What it does
<code>mkdir</code>	Makes a new folder called <code>Research</code> .
<code>cd</code>	Moves you into a folder. <code>cd</code> stands for <i>change directory</i> , which is the same as opening a folder in a file window.
<code>git clone</code>	Downloads a copy of the project from the internet into a new folder called <code>NSDF-Data</code> .

Checkpoint

Type `ls` and press Enter. You are now inside the `NSDF-Data` folder (your prompt mentions it), so the list shows the project's own folders and files, such as `python`, `R76`, `docs` and `README.md`.

Step 5. Create your analysis environment

An environment is a sealed box of programs with fixed versions. We make one for this project, called `darkmatter_cli_env`. Type these lines one at a time, pressing Enter after each. The third line takes several minutes and prints a lot of text: wait for the prompt to come back.

```
conda create -n darkmatter_cli_env python=3.10 -y
conda activate darkmatter_cli_env
python -m pip install nsdf-dark-matter==0.3.0 nsdf-dark-matter-cli==0.5.0
python -m pip install numpy==2.2.6 matplotlib==3.10.7 h5py pytest ipykernel
python -m pip install jupyterlab
```

What these lines do

Line	What it does
<code>conda create</code>	Makes a new, empty environment called <code>darkmatter_cli_env</code> , with Python 3.10 inside it.
<code>conda activate</code>	Switches that environment on. While it is on, your prompt starts with <code>(darkmatter_cli_env)</code> .
<code>pip install nsdf-dark-matter...</code>	Installs the software that reads the detector data.
<code>pip install numpy...</code>	Installs software for numbers, plots and checking that everything works.
<code>pip install jupyterlab</code>	Installs Jupyter, the notebook program you will use later.

Tip

The project folder also has a file called `requirements.txt` that lists the same software versions. You do **not** need it: the lines above do the whole job, and they work the same on every computer.

Tip

Every time you open a new terminal, run `conda activate darkmatter_cli_env` first. When it is active, the start of each line shows `(darkmatter_cli_env)`.

Checkpoint

The last line of the output is a message, not an error, and the `(darkmatter_cli_env)` label is at the start of your prompt.

Step 6. Check that everything works

First, the tests. They use made-up data, so they need no download. Type each line and press Enter:

```
conda activate darkmatter_cli_env
cd ~/Research/NSDF-Data/python
```

```
python -m pytest -q
```

Checkpoint

The last line says 52 passed (it can be a larger number later, which is also fine). If it says failed, stop and ask the project lead, and do not change any files.

Then, the data tool:

```
nsdf-cli version
```

Checkpoint

It prints NSDF Dark Matter CLI: 0.5.0 (or a later version).

Finally, the notebook program:

```
jupyter lab --version
```

Checkpoint

It prints a version number, such as 4.4.0. If it says jupyter-lab is not found, run `python -m pip install jupyterlab` and try again.

What these commands do

Line	What it does
<code>conda activate</code>	Switches your environment on. Do this in every new terminal.
<code>cd</code>	Moves into the python folder of the project.
<code>python -m pytest -q</code>	Runs the project's built-in self-checks. The <code>-q</code> just means "keep the output short". 52 passed means every check worked.
<code>nsdf-cli version, jupyter lab --version</code>	Each one only asks a program to say which version it is. If it answers, it is installed.

Step 7. Let Jupyter notebooks use your environment

Jupyter is the notebook program you will use. Register your environment with it once:

```
python -m ipykernel install --user --name darkmatter_cli_env
```

Checkpoint

It prints a line that starts with Installed kernelspec darkmatter_cli_env.

Step 8. Get permission to save your work

You will not change the main project. You will save your work on your own **branch**, and for that the lead must give you access:

1. Make a free account at github.com if you do not have one.
2. Send your GitHub username to the project lead. They will add you to the project as a collaborator.
3. Once you have accepted the invitation, tell Git your name and email, so your work is labelled as yours. Use your own details:

```
git config --global user.name "Your Name"
git config --global user.email "you@example.com"
```

4. Create your personal branch (your own space to save work, separate from the main project). Use your own name, without spaces, in place of yourname:

```
cd ~/Research/NSDF-Data
git checkout -b student-yourname
```

Checkpoint

The terminal shows Switched to a new branch 'student-yourname'.

Rules for keeping your work safe

- **Never work on master or develop.** Those are the shared versions. Work only on your student- branch.
- **Never commit data.** The raw files in the idx folder are large and not part of the project. Download only from your home folder, never from inside NSDF-Data.
- **Do not run 07221203_2025_dump1_noise.ipynb** unless the project lead says it is fine. It overwrites a shared archive file.
- **Save often**, and commit your work when a piece is finished (see the first analysis guide).

You are done when

- ☐ Your terminal opens and `git --version` prints a version.
- ☐ `conda --version` prints a version, in a new terminal.
- ☐ `ls ~/Research` lists NSDF-Data.
- ☐ `python -m pytest -q` in the python folder ends with 52 passed.
- ☐ `nsdf-cli version` prints a version.
- ☐ `jupyter lab --version` prints a version.
- ☐ `jupyter kernelspec list` lists `darkmatter_cli_env`.
- ☐ `git branch` shows * student-yourname (after access is granted).

Next: *First analysis* (the guide for Linux).

If something goes wrong

1. Read the **last line** of the message. It usually says what is wrong.
2. Close the terminal, open a new one, and run `conda activate darkmatter_cli_env` again. Many problems are just the wrong environment.
3. Copy the command you ran and the message it printed, and send them to the project lead. A screenshot is also fine.

Where to get help

Anthony Villano, project lead: anthony.villano@ucdenver.edu

When you write, include the step number, the command you typed, and the last few lines the computer printed. A screenshot helps. Nobody will be annoyed by a question about a step that did not work.
